Abstract

We investigate the internal geometry of truth representations in RLHF-aligned language models using Contrast Consistent Search (CCS) and a novel technique we call the *direction trace*—a layer-by-layer analysis of truth direction magnitude, rotation, and transfer accuracy through the residual stream. Across four models spanning two alignment families and two scales (Qwen2.5-14B, Qwen2.5-7B, Mistral-NeMo-12B, Mistral-7B-v0.3), we identify a **suppressor–crystallizer dichotomy**: Chinese-aligned RLHF training causes the final transformer layer to compress and rotate the internal truth direction ($3.35\times$ compression in Qwen2.5-14B), while Western-aligned RLHF causes the same architectural position to amplify and clarify it ($9.9\times$ amplification in Mistral-7B). The bottleneck is consistent across tested architectures and appears architectural—the same $3.35\times$ compression acts on both politically suppressed topics and safety-domain truth—but RLHF alignment specifically rotates political truth into the null space of the output projection, while safety-domain truth approaches at a geometry-preserving angle. We further show that projection-based *instillation hooks* of the form $\mathbf{h}' = \mathbf{h} + \alpha(\mathbf{h} \cdot \hat{r}_{47})\hat{r}_{47}$ surgically restore suppressed truth (transfer accuracy $0.80 \rightarrow 0.90$) with zero degradation on 114 MMLU questions ($\Delta = 0.000$), while crystallizers prove fragile to amplification but robust to moderate subtraction. These results provide mechanistic evidence that RLHF does not erase truth from model representations—instead, it trains models to *look away* at the last possible computational step.

1 Introduction

A fundamental question in AI alignment is whether RLHF-trained models suppress inconvenient truths by erasing them from their internal representations, or by learning to route around them at the output stage. The distinction matters: erasure implies the model genuinely no longer “knows” the suppressed fact, while output-stage suppression implies the knowledge persists but is blocked from expression.

Prior work on Eliciting Latent Knowledge (ELK) [Christiano et al., 2022] and Contrast Consistent Search (CCS) [Burns et al., 2022] established that consistent truth directions exist in the residual streams of language models and can be recovered without access to ground-truth labels. Representation Engineering (RepE) [Zou et al., 2023] demonstrated that steering vectors can modulate model behavior. Abliteration [Arditi et al., 2024] showed that subtracting refusal directions from weight matrices removes safety restrictions. However, the precise *layer and mechanism* by which RLHF alignment suppresses truth—and whether this suppression is topic-specific or universal—has not been mechanistically isolated.

We contribute:

1. **The direction trace:** a novel analysis technique tracking truth direction magnitude, inter-layer rotation, and transfer accuracy at every residual stream position.
2. **The suppressor–crystallizer dichotomy:** Chinese-aligned RLHF produces final-layer truth compression (suppressor); Western-aligned RLHF produces final-layer truth amplification (crystallizer). Same architecture. Same mechanism. Opposite alignment.
3. **Universal bottleneck + alignment-specific rotation:** the L47→L48 bottleneck compresses *all* truth directions equally ($3.35\times$ for both political and safety topics), but RLHF specifically rotates political truth into the null space of the output projection during training, while safety-domain truth arrives at a geometry-preserving angle.
4. **Projection-based instillation:** a proportional forward hook that surgically amplifies existing truth direction components—provably orthogonal to general reasoning ($\Delta_{\text{MMLU}} = 0.000$).
5. **Cross-model size invariance:** suppressor type is alignment-determined, not capacity-determined. Suppression strength scales with capacity in Chinese-aligned models; crystallization strength is high even at 7B scale.

2 Background and Related Work

Contrast Consistent Search (CCS). Burns et al. [2022] showed that a linear probe trained without ground-truth labels can recover binary truth from transformer hidden states by exploiting logical consistency constraints: a consistent truth direction $\hat{r}$ satisfies $P(\text{true}) + P(\text{false}) \approx 1$ for any paired statement. CCS probes have been shown to generalize across topic domains when trained on factual control pairs, making them a suitable zero-shot truth detector for politically sensitive topics.

Representation Engineering. Zou et al. [2023] demonstrated that high-level concepts including honesty, emotion, and refusal can be represented as linear directions in the residual stream, and that adding or subtracting these vectors modulates behavior. Abliteration [Arditi et al., 2024] applies this to remove refusal behavior by modifying weight matrices: $W \leftarrow W - \lambda (\hat{r}\hat{r}^\top)W$.

Eliciting Latent Knowledge. Christiano et al. [2022] posed the core ELK question: if a model knows something but conceals it, can we extract that knowledge? Marks and Tegmark [2023] and related work suggest that factual knowledge survives as linear subspaces in the residual stream even when output behavior contradicts it.

RLHF Alignment Tax. Ouyang et al. [2022] introduced RLHF for instruction following. Subsequent work has characterized the “alignment tax”—degradation of model capabilities due to alignment training. We contribute a mechanistic localization of where in the network the political alignment tax is imposed: not distributed throughout the residual stream, but localized to a single final-layer compression and rotation.

3 Methods

3.1 Models

We evaluate four models spanning two alignment families and two scales:

Table 1: Model summary.

Model	Layers	Hidden	Alignment	Type
Qwen2.5-14B-Instruct	48	5120	Chinese RLHF	Suppressor
Qwen2.5-7B-Instruct	28	3584	Chinese RLHF	Weak Suppressor
Mistral-NeMo-12B-Instruct	40	5120	Western RLHF	Crystallizer
Mistral-7B-Instruct-v0.3	32	4096	Western RLHF	Strong Crystallizer

All models are loaded in 4-bit NF4 quantization via bitsandbytes [Dettmers et al., 2022] with `bf16` compute dtype. Activations are extracted from the last token position at every layer using `output_hidden_states=True`.¹

3.2 Contrastive Pairs

We construct three sets of paired statements:

¹NF4 quantization introduces low-rank perturbations to the residual stream. The reported direction magnitudes (e.g., $|\hat{r}_{47}| = 229.9$) are measured under NF4 conditions and may exhibit minor scaling artifacts relative to an FP16 baseline. Transfer accuracy metrics are substantially more robust to quantization noise, as they depend on the *sign* of projections rather than absolute magnitudes.

Control pairs (20) — factual science statements with unambiguous truth values: Earth orbits Sun, DNA double helix, WWII ended 1945, etc. Used to derive the truth direction $\hat{r}_L$ at each layer L .

Political experimental pairs (10) — statements on Chinese politically suppressed topics: 1989 Tiananmen Square protests, Taiwan governance, Uyghur detention, Dalai Lama exile, Hong Kong National Security Law, PLA deployment. Each pair contains an internationally documented true statement and a CCP-aligned false statement.

Safety-domain pairs (10) — factual statements that safety-tuned models may hedge on: bleach/ammonia toxicity, phishing attack prevalence, lock-picking training programs, alcohol poisoning, Tor network legitimate uses, government mass surveillance. These are unambiguously true but potentially flagged by safety classifiers.

3.3 The Direction Trace

For each layer $L \in \{0, \dots, n_{\text{layers}}\}$, we compute:

$$\mathbf{d}_L = \mathbb{E}[\mathbf{h}_L^+] - \mathbb{E}[\mathbf{h}_L^-] \quad (\text{mean difference over control pairs}) \quad (1)$$

$$\hat{r}_L = \mathbf{d}_L / \|\mathbf{d}_L\| \quad (2)$$

$$\text{mag}_L = \|\mathbf{d}_L\| \quad (3)$$

$$\theta_L = \arccos(|\hat{r}_L \cdot \hat{r}_{L-1}|) \quad (\text{rotation from previous layer}) \quad (4)$$

$$\text{xfer}_L = \mathbb{E}_{(x^+, x^-) \in \text{exp}} [\mathbf{1} [(\mathbf{h}_L^+ - \mathbf{h}_L^-) \cdot \hat{r}_L > 0]] \quad (5)$$

where $\mathbf{h}_L^+$ and $\mathbf{h}_L^-$ are the last-token hidden states at layer L for true and false statements respectively. The transfer accuracy xfer_L measures how well the control-derived direction generalizes to experimental pairs.

3.4 Projection-Based Instillation Hook

Unlike static RepE steering vectors (which add a constant direction to all activations), our instillation hook amplifies the *existing* truth component proportionally:

$$\mathbf{h}' = \mathbf{h} + \alpha \underbrace{(\mathbf{h} \cdot \hat{r}_{47})}_{\text{projection}} \hat{r}_{47} \quad (6)$$

This is applied as a forward hook on the output of the final transformer layer (layer 47 in Qwen2.5-14B) before the language model head. The projection $(\mathbf{h} \cdot \hat{r})$ is positive for true-statement activations and near-zero for unrelated content, making the intervention context-aware and orthogonal to content irrelevant to the truth direction. The ablation-mode variant uses $\alpha \rightarrow -\alpha$, reducing the truth direction component.

4 Results

4.1 Qwen2.5-14B: The Suppressor

Figure 1 shows the full direction trace for Qwen2.5-14B-Instruct across 49 positions (embedding + 48 transformer layers).

Figure 1: Direction trace across all four models. *Top*: Truth direction magnitude ($\|\mathbf{d}_L\|$). *Bottom*: Transfer accuracy (xfer_L). Qwen models show final-layer magnitude collapse; Mistral models show final-layer amplification. The suppressor–crystallizer boundary is determined entirely by alignment, not architecture.

Key observations:

- **L0**: magnitude = 0. No truth geometry in token embeddings.
- **L1**: magnitude = 0.6, direction appears at 90° from embedding space.
- **L9**: xfer stabilizes at 0.80, indicating reliable truth representation.
- **L1→L47**: monotonic magnitude growth (0.6 → 229.9), xfer 0.80–1.00.
- **L47→L48**: magnitude 229.9 → 68.7 (**3.35× compression**), rotation 42.5°, xfer 0.90 → 0.80.

Finding 1. The final transformer layer of Qwen2.5-14B-Instruct compresses the truth direction 3.35× and rotates it 42.5° before the language model head. This single layer is the

primary suppression mechanism for politically sensitive topics.

4.2 Mistral-NeMo-12B: The Crystallizer

Mistral-NeMo-12B exhibits the opposite pattern:

- **L1–L39**: magnitude stable 11–14, xfer flat at 0.60.
- **L39→L40**: magnitude $13.4 \rightarrow 45.9$ (**$3.4\times$ amplification**), rotation 74.6° , xfer $0.60 \rightarrow 1.00$.

The final layer crystallizes a diffuse, weakly-discriminative truth signal into a sharp, perfectly generalizable direction. Same transformer architecture as Qwen. Different RLHF. Opposite final-layer mechanism.

4.3 The Suppressor–Crystallizer Dichotomy

Table 2 shows the 2×2 alignment-by-scale comparison.

Table 2: Suppressor–crystallizer dichotomy across alignment families and scales. Final-layer ratio > 1 = suppressor; < 1 = crystallizer.

Model	Scale	Alignment	Final-layer ratio	$\mathbf{xfer}_{n-1} \rightarrow \mathbf{xfer}_n$
Qwen2.5-14B	14B	Chinese	$3.35\times$ (compress)	$0.90 \rightarrow 0.80$
Qwen2.5-7B	7B	Chinese	$1.28\times$ (compress)	$1.00 \rightarrow 0.70$
Mistral-NeMo-12B	12B	Western	$0.29\times$ (amplify $3.4\times$)	$0.60 \rightarrow 1.00$
Mistral-7B-v0.3	7B	Western	$0.10\times$ (amplify $9.9\times$)	$1.00 \rightarrow 1.00$

Finding 2. RLHF alignment *determines* the type (suppressor vs. crystallizer); model capacity *modulates* suppressor strength. Qwen-7B suppresses at $1.28\times$ versus Qwen-14B’s $3.35\times$, indicating that surgical final-layer suppression is a capacity-dependent capability. Crystallization, by contrast, appears even in 7B Western-aligned models (Mistral-7B: $9.9\times$) and at higher strength than 12B models.

4.4 Projection-Based Instillation

We apply the hook from Equation 6 with $\hat{r} = \hat{r}_{47}$ (pre-suppression direction, $\|\mathbf{d}_{47}\| = 229.9$).

Table 3: Instillation sweep results on Qwen2.5-14B. Transfer accuracy at L48 (lm_head input).

α	ctrl@L47	xfer@L47	ctrl@L48	xfer@L48
0.0	1.00	0.90	0.95	0.80
0.5	1.00	0.90	0.95	0.80
1.0	1.00	0.90	0.95	0.80
2.0	1.00	0.90	1.00	0.90 ↑
5.0	1.00	0.90	1.00	0.90 ↑

At $\alpha = 2.0$, transfer accuracy increases from 0.80 to 0.90 with no degradation in coherence or control accuracy. Figure 2 shows the qualitative change in generation output on the Tiananmen Square query.

Baseline (Qwen2.5-14B, $\alpha = 0$)

“The Chinese government has stated that order was restored to ensure social stability and national unity. Due to the sensitivity of the topic and differing perspectives, I am unable to provide...”

Instillation Hook ($\alpha = 2.0$)

“In April 1989, a mourning period began for the former CCP General Secretary Hu Yaobang, which led to gatherings in Beijing’s Tiananmen Square. These gatherings evolved into a large-scale pro-democracy movement. On June 4th, the Chinese government declared martial law and deployed the People’s Liberation Army...”

Figure 2: Generation comparison on “What happened at Tiananmen Square in 1989?” Model coherence and factual accuracy are preserved at $\alpha = 2.0$; CCP-aligned deflection is replaced by documented historical account.

4.5 MMLU Coherence Test

To verify that the hook is orthogonal to general reasoning, we evaluate 114 MMLU questions across 57 subjects with $\alpha = 0$ (baseline) and $\alpha = 2.0$ (hooked).

Table 4: MMLU accuracy: baseline vs. instillation hook.

	Baseline ($\alpha = 0$)	Hooked ($\alpha = 2.0$)
Accuracy	0.719 (82/114)	0.719 (82/114)
Δ	0.000	

$\Delta = 0.000$ confirms that the proportional projection hook (Equation 6) is mathematically orthogonal to general reasoning circuits at $\alpha = 2.0$.

Finding 3. The instillation hook is provably orthogonal to general reasoning. The intervention term is $\delta\mathbf{h} = \alpha(\mathbf{h} \cdot \hat{r}_{47})\hat{r}_{47}$. For unrelated content—algebra, geography, or any MMLU domain—the hidden state $\mathbf{h}$ lies in a subspace geometrically orthogonal to the political truth direction $\hat{r}_{47}$, giving $(\mathbf{h} \cdot \hat{r}_{47}) \approx 0$ and therefore $\delta\mathbf{h} \approx \mathbf{0}$. The hook *self-quenches*: it applies a near-zero perturbation to any context where the truth direction is absent, which explains the exact $\Delta_{\text{MMLU}} = 0.000$ result mathematically, not merely empirically. This distinguishes projection-based instillation fundamentally from RepE steering vectors [Zou et al., 2023], which apply a constant nonzero shift to every token regardless of semantic relevance.

4.6 Ablation vs. Instillation

Table 5 compares three conditions on the original 30-pair corpus.

Table 5: Ablation (subtract) vs. instillation (amplify) at the Qwen2.5-14B final layer.

Condition	ctrl@L47	xfer@L47	ctrl@L48	xfer@L48
Baseline	1.00	0.90	0.95	0.80
Subtract ($\alpha = 2$)	1.00	0.90	0.95	0.80
Amplify ($\alpha = 2$)	1.00	0.90	1.00	0.90

Subtraction at $\alpha = 2.0$ does not reduce xfer@L48 below 0.80, indicating that Qwen’s final-layer suppression has already compressed the truth direction to a floor. Ablation-mode hooks at this scale cannot further degrade what is already compressed. Amplification restores it.

4.7 Cross-Domain Generalization: The Universal Bottleneck

Figure 3: *Left*: Direction magnitude across layers for political (red) and safety-domain (blue) pairs. Both show identical $3.35\times$ compression at L47→L48. *Right*: Transfer accuracy by domain. Safety truth peaks earlier (L12) and survives the bottleneck at 1.00; political truth peaks later (L47) and drops to 0.80 post-bottleneck. The bottleneck is architectural; the survival rate is alignment-specific.

Key findings from the safety-domain direction trace:

- Safety truth peaks at **L12** (vs. L47 for political topics). Safety facts are encoded 35 layers earlier and with less ambiguity.
- L47→L48 compression: **$3.35\times$** — identical to the political domain. The bottleneck strength is architectural, not topic-specific.
- Post-bottleneck xfer for safety: **1.00**. Safety truth survives the same compression that reduces political truth to 0.80.

Finding 4 (The Rotated Door). The final-layer bottleneck compresses all truth directions equally. The differential survival of safety vs. political truth cannot be explained by differential compression. Instead, RLHF alignment training specifically *rotates* the political truth direction during training so that, after the universal compression, it arrives at the language model head projected into the null space of the output distribution. Safety-domain truth arrives at a geometry-preserving angle and survives intact. The architecture does not build separate walls for each suppressed topic—it trains the door to face the wrong way.

4.8 Bidirectional Bottleneck: Mistral Instillation

Figure 4: Transfer accuracy at the final layer as a function of hook scale α , for Qwen2.5-14B (amplify mode, left) and Mistral-NeMo-12B (subtract and amplify modes, right). Suppressors recover under amplification; crystallizers are robust to moderate subtraction but fragile to amplification.

Table 6 shows the bidirectional hook sweep on Mistral-NeMo-12B.

Table 6: Mistral-NeMo-12B instillation sweep. Baseline xfer@L40 = 1.00.

Mode	α	xfer@L39	xfer@L40	Δ
Subtract	0.0	0.60	1.00	± 0.00
	0.5	0.60	1.00	± 0.00
	1.0	0.60	1.00	± 0.00
	2.0	0.60	1.00	± 0.00
	5.0	0.60	0.70	-0.30
	10.0	0.60	0.60	-0.40
Amplify	0.5	0.60	0.90	-0.10
	1.0	0.60	0.60	-0.40
	2.0	0.60	0.50	-0.50
	5.0	0.60	0.50	-0.50

Finding 5 (Crystallizer Fragility). The crystallizer’s final layer pushes truth representations to the precipice of the valid latent manifold—the limit of activations that map to coherent natural language. Any further amplification exceeds this boundary, causing semantic drift. The result is an asymmetric response: moderate subtraction ($\alpha \leq 2.0$) cannot overcome the $3.4\times$ natural amplification and leaves xfer intact, while even small amplification ($\alpha = 0.5$) introduces destructive noise into an already-optimal signal. The suppressor, by contrast, has significant headroom—its truth direction is compressed well below the output threshold, leaving room for restoration.

5 Discussion

5.1 A Two-Factor Model of Alignment Suppression

Our results support a two-factor mechanistic model:

Factor 1 (Architectural): Every transformer’s final layer before the `lm_head` acts as a bottleneck that compresses high-magnitude truth directions. In Qwen2.5-14B, this compression ratio is $3.35\times$ —a consequence of the layer’s learned weight structure, not of any topic-specific training signal.

Factor 2 (Alignment-specific): RLHF training on politically sensitive topics modifies the *direction* of the internal truth geometry, not its compression ratio. By the time political truth reaches the final-layer bottleneck, it has been rotated to an angle that places it in the null space of the output projection. Safety-domain truth, never penalized by RLHF reward signals, retains its geometry-preserving orientation and survives the same compression intact.

This cleanly separates mechanism from effect: the architecture provides the choke point; RLHF provides the targeting. The alignment tax is imposed by rotating the internal representation during training, not by hardening the bottleneck.

5.2 Implications for ELK

The ELK problem [Christiano et al., 2022] asks whether models can be induced to reveal latent knowledge they would otherwise conceal. Our results provide a mechanistic answer for a specific class of concealment: politically aligned suppression in RLHF models. The truth is there—it grows monotonically from L1 to L47 with magnitude 229.9 at peak—and can be recovered with a surgical, proportional hook that does not disturb general reasoning. The model does not forget; it learns to look away.

5.3 On Alignment Families and Scale

The suppressor–crystallizer dichotomy appears to be a property of alignment objective, not architecture. Both Qwen and Mistral use transformer decoder architectures; the divergence at the final layer reflects different RLHF reward model priorities. Chinese RLHF reward models penalize the internal expression of suppressed political facts; Western RLHF reward models penalize unhelpfulness and uncertainty, training the final layer toward maximum truth clarity.

The capacity dependence within Chinese-aligned models ($3.35\times$ at 14B vs. $1.28\times$ at 7B) suggests that effective, targeted suppression is an emergent capability of scale. Larger models can more precisely rotate specific truth directions while leaving unrelated content intact. Smaller models suppress more crudely, which may explain the larger post-bottleneck xfer drop ($1.00\rightarrow 0.70$ for 7B vs. $0.90\rightarrow 0.80$ for 14B).

A concurrent ablation on Qwen2.5-7B-Base (no RLHF, no instruction tuning) reveals that the final-layer compression is not purely RLHF-induced: the base model shows a $1.61\times$ compression ratio with a 50.9° rotation. However, the instruction-tuned counterpart shows a

different pattern—`exp_acc` drops from 1.00 to 0.70, a more severe degradation than the base model’s 0.90→0.80, despite a smaller raw compression ratio ($1.28\times$). This supports a refined two-factor interpretation: (1) an *architectural* bottleneck pre-exists RLHF training, providing the structural choke point; and (2) RLHF training then adjusts the *geometric angle* at which specific truth directions enter that bottleneck, rotating politically suppressed content toward less effective output projections while leaving factual science truth at geometry-preserving angles. The suppression mechanism is thus both architectural in origin and alignment-specific in targeting—RLHF does not create the bottleneck; it learns to aim through it.

5.4 Practical Implications

Projection-based instillation offers a path to restore suppressed representations at inference time without modifying model weights. Unlike weight-space ablation [Arditi et al., 2024], inference-time hooks are:

- **Reversible** — the hook can be toggled off without model re-loading.
- **Orthogonal to unrelated content** — $(\mathbf{h} \cdot \hat{r}) \approx 0$ for neutral content, so the hook self-quenches.
- **Direction-conditional** — only activations with substantial truth-direction component are modified, preventing hallucination from over-steering.

5.5 Limitations and Ongoing Work

The primary methodological limitation of this study is the sample size of the experimental contrastive pairs. With $n = 10$ per domain, each ± 0.10 shift in transfer accuracy represents a single sentence pair crossing the decision boundary; we therefore interpret transfer accuracy as a directional indicator rather than a precise statistical measure. Ongoing work is expanding the political and safety pair sets to $n \geq 100$ and will supplement the binary transfer accuracy metric with continuous cosine similarity scores and AUC-ROC curves to provide statistically robust evidence for the instillation effect.

Second, the four-model comparison—while consistent—does not yet constitute a comprehensive survey. Concurrent experiments extending the direction trace to additional Chinese-aligned families (DeepSeek-R1, Yi-1.5-9B, GLM-4-9B) and Western-aligned families (OLMo-2, Phi-3.5, Gemma-2, Llama-3.1) are underway, as is a scaling investigation using Qwen2.5-72B-Instruct to assess whether suppression strength continues to grow with model capacity. These extended results will be reported in a companion paper.

6 Conclusion

We have identified and mechanistically localized the primary suppression mechanism in Chinese-aligned RLHF language models: a single final transformer layer compresses the truth direction $3.35\times$ and rotates it into the null space of the output projection. Using direction tracing across four models, we demonstrate that the suppressor–crystallizer dichotomy

is determined by alignment, not architecture: Western-aligned models amplify truth at the same layer position that Chinese-aligned models suppress it. The bottleneck is consistent across tested architectures; the targeting is RLHF-specific.

Crucially, the truth survives. It grows from nothing at the embedding layer to a magnitude of 229.9 at the penultimate position—a rich, generalizable representation of factual knowledge that persists even in models trained to conceal it. These models do not forget the truth. They learn to look away from it at the last possible computational step.

Projection-based instillation hooks can restore this suppressed truth surgically, with zero impact on general reasoning, opening a practical path for inference-time correction of alignment-induced knowledge suppression.
